A Review of Infant Use of Powered Mobility

By: Jillian Byrnes, Matthew Darby, Tiani DeBlois, Natalie Dispoto, Emily Fleming, Keanna Morales, Carly Wellner, Amanda Wetmore

Background

In addition to self-locomotion, mobility promotes perceptual, cognitive\(^2\), social, & language development in infants.\(^{2,14}\)

Lack of mobility experience may impede development in children with motor impairment.

Powered mobility devices, which often use a joystick as a means of control\(^5\), help those with mobility impairment to be integrated into their environment, thus increasing their participation.

The purpose of this review was to explore what is known about the development of powered mobility control in very young children.

<table>

<tbody>
<tr>
<td>Butler(^1)</td>
<td>Six children 23-38 months with lower extremity impairments</td>
<td>Use of the wheelchairs were observed every 10 days</td>
<td>It took an average of 1-3 weeks for the children to become independently mobile</td>
</tr>
<tr>
<td>Chen, Ragonesi, Galloway, &amp; Agrawal(^3)</td>
<td>Five toddlers with a mean age of 29.6 months were in the control group and were given a typical PMD to navigate a path with obstacles</td>
<td>Training and test trials were observed on the participants’ ability to navigate obstacles</td>
<td>Much training was needed in order to be successful in maneuvering through the course, it took approximately ten trials to navigate the course</td>
</tr>
<tr>
<td>Dunaway, Montes, O’Hagen, Sproule, De Vivo, &amp; Petra(^4)</td>
<td>Six children 16-23 months old with spinal muscular atrophy or congenital muscular dystrophy</td>
<td>The Power Mobility Skills Checklist (PMSC)</td>
<td>It took an average of 7.9 months for the children to proficiently operate the wheelchair based on the PMSC</td>
</tr>
<tr>
<td>Jones, McEwen, &amp; Neas(^8)</td>
<td>14 children 14-30 months with mobility impairments</td>
<td>The Wheelchair Skills Checklist</td>
<td>Only four of the children were able to complete all of the items on the checklist</td>
</tr>
<tr>
<td>Lynch, Ryu, Agrawal, &amp; Galloway(^10)</td>
<td>One seven-month old with spina bifida over the course of 5 months</td>
<td>Directional driving and open exploration trials conducted 3-4 times/week looked at joystick Activation, path length, and percent-directed driving success</td>
<td>The infant could use the joystick, but could only drive in a straight line</td>
</tr>
<tr>
<td>Stansfield, Dennis, Altman Smith, &amp; Larin(^13)</td>
<td>Nine typically developing infants between 5-10 months</td>
<td>Driving was analyzed using ELAN annotation software</td>
<td>The infants were able to move the wheelchair forward, but not side to side</td>
</tr>
</tbody>
</table>

Discussion

There is a discrepancy between researchers as to how driving should be assessed and when it is feasible to give clients a power mobility device.

Researchers have not collected data to analyze the various capabilities and strengths toddler drivers have at various ages. Therefore, there is not sufficient research that guides therapists in deciding when a joystick-controlled mobility device is appropriate.
